Auto Ticket Classification using FLOW DESIGNER

Team ID	SWTID-2026-4750
Project Type	ServiceNow Flow Designer workflow

1. Project Description

Auto Ticket Classification using Flow Designer is intended to route or categorize incoming tickets automatically based on configured conditions. The flow evaluates ticket information and performs the actions defined by the project team. Exact classification fields and rules should match the implemented ServiceNow flow.

Problem Statement

Manually reviewing and categorizing every incoming ticket can take time and may lead to inconsistent routing. The project aims to reduce repetitive manual work by applying predefined conditions through a workflow.

Objectives

• Classify incoming tickets using configured conditions.

• Improve consistency in ticket categorization.

• Reduce repetitive manual steps.

• Make flow execution and results easier to review.

2. Proposed Workflow

Step	Workflow activity	Expected result
1	A ticket is created or updated (configured trigger).	Flow starts when trigger conditions match.
2	Read relevant ticket fields.	Ticket details are available for evaluation.
3	Evaluate conditions defined in Flow Designer.	A matching classification path is selected.
4	Update classification/category or routing fields as configured.	Ticket is categorized or routed.
5	Review execution details.	Successful run or error can be checked.

3. Technical Design

Platform: ServiceNow Flow Designer.

Input: Ticket/incident record and the fields used by the configured conditions.

Processing: Trigger → condition checks → classification path → configured update/action.

Output: Updated ticket classification or routing information, depending on the actual flow configuration.

The exact field names, trigger, categories, actions and screenshots must be inserted from the team's implementation; they were not supplied in the request.

4. Implementation Procedure

1. Open the authorized ServiceNow instance.
2. Navigate to Flow Designer.
3. Create or open the Auto Ticket Classification flow.
4. Configure the trigger for the relevant ticket record.
5. Add conditions for the ticket details used by the classification logic.
6. Configure the actions that set the required category or routing fields.
7. Save and activate the flow after checking the configuration.
8. Run a test ticket and inspect the execution details.

5. Testing and Validation

Test	Action	Expected result	Status
Valid ticket	Submit a ticket matching a configured condition.	Correct classification path runs.	To be tested
Different category	Submit a ticket matching another condition.	Corresponding path runs.	To be tested
No matching condition	Submit a ticket outside configured conditions.	Configured default/else behavior occurs, if present.	To be tested
Execution review	Inspect flow execution details.	Success or error is recorded.	To be tested

6. Requirements and Limitations

Requirements: Authorized ServiceNow access, Flow Designer permission, and permission to create or test ticket records.

Limitations: The workflow can only classify based on the fields and rules configured. Incorrect or incomplete ticket details may prevent the intended classification. Access permissions and instance configuration may affect execution.

7. Conclusion

The project demonstrates a workflow-based approach to ticket classification using ServiceNow Flow Designer. By applying configured conditions and actions, it can support more consistent ticket categorization and reduce repetitive manual handling. Final conclusions should be updated after the implemented flow has been tested.

8. Items to Add Before Submission

■ Screenshots of the actual flow, trigger, conditions and actions.

■ Actual classification categories and field names.

■ Test evidence and observed results.

■ Authorized instance URL, repository link and demo video link, if applicable.
